This document provides the analysis and rationale for migrating to Debian as the projects upstream distribution. This change was completed in late-2018 and as such all releases since v2019 have been based on Debian.

## <sup>16</sup> Why was Apertis based on the Debian/Ubuntu <sup>17</sup> ecosystem

At the beginning of Apertis, a few platforms were considered for the base of 18 Apertis: MeeGo, Tizen, OpenEmbedded Core, Debian and Ubuntu. A choice 19 of Debian/Ubuntu ecosystem was based on Debian being 'one of the oldest and 20 largest (most inclusive of OSS packages), and one of the first Linux distribu-21 tions to feature an ARM port', providing 'a very solid distribution baseline' 22 and 'a high degree of robustness against the involvement or not of individual 23 contributing companies', while Ubuntu bases on Debian but adds value impor-24 tant for Apertis (see below). Another point against the other alternatives (e.g. 25 OpenEmbedded Core) was that Collabora and Bosch have already invested into 26 Open Build System infrastructure, while Yocto/OpenEmbedded has its own 27 build infrastructure and tools not compatible with OBS. 28

Another important point was that Collabora employed and continues to employ many Debian package maintainers, who contribute to key OSS middleware
packages within both the Debian and Ubuntu projects directly, which presented
a serious benefit over other alternatives.

# <sup>33</sup> Why was Ubuntu taken as the direct upstream <sup>34</sup> rather than Debian

When the decision to use Ubuntu was taken, Ubuntu had several benefits over Debian. Especially taking into account the initial goal or having an update cycle of around 6 month of the baseline platform.

Debian only releases once every 2 to 2.5 years, while Ubuntu does release every 38 6 months with every 4th of those being a long-term support release. This 39 means that the only way of doing a refresh every 6 months based directly on 40 Debian would mean creating a snapshots of Debian testing, stabilising that and 41 providing security support for it. Doing that purely for Apertis would of course 42 require a significant amount of resources, but more importantly, it is essentially 43 what Ubuntu is already doing. This made Ubuntu more suitable as a baseline 44 for a 6 month update cycle. 45

<sup>46</sup> Furthermore, the Linaro initiative used Ubuntu as a reference distribution for
<sup>47</sup> all of their validation of hardware enablement. Linaro and Canonical engineers
<sup>48</sup> actively integrated the latest work from Linaro and SoC vendors, including
<sup>49</sup> Freescale, into Ubuntu. By using Ubuntu as a base Apertis could benefit from
<sup>50</sup> and build on this work.

At the time, Ubuntu was the *de facto* upstream of AppArmor, this included patched kernels to enable latest features (D-Bus mediation, socket mediation, ptrace mediation, etc.) as well as changes to individual packages to improve their apparmor profiles.

## 55 What has changed

While doing two base platform refreshes every year has been successful, the 56 users of Apertis weren't actually set up to follow in such a fast cycle. On top 57 of that the non-LTS releases of Ubuntu limited their security support cycle 58 from 18 months after release to only 9 months after release. In other words the 59 upgrade window since the start of the Apertis project went from around one year 60 after a platform refresh to only 3 months after each platform refresh before the 61 upstream security support end. Such a short time-frame is not achievable with 62 the required updates and validation that are required before a major product 63 rollout. 64

<sup>65</sup> Due to the policy changes, it was decided to base the Apertis platform on LTS <sup>66</sup> versions rather than refreshing on each version, utilising the longer security <sup>67</sup> support period on these LTS releases. Apertis was last rebased onto the Ubuntu <sup>68</sup> 16.04 LTS release (codenamed "Xenial Xerus").

<sup>69</sup> Ubuntu and Linaro are no longer collaborating together as they were. Linaro <sup>70</sup> are now supporting various boards using a Debian based release, directly con-<sup>71</sup> tributing to Debian and no longer supporting Ubuntu.

The infrastructure required by Apparmor has matured to the point where the 72

features used by Apertis have been upstreamed and as such Apertis is no longer 73 tied to Ubuntu in this regard. 74

112

113

#### • Benefits 76 - Debian is a community project, with no single company driving its 77 development 78 - Maintenance of components we rely on is not tied to Canonical's 79 commercial strategies 80 Security support for at least 5 years since the initial stretch release 81 via the Debian LTS project 82 More direct contribution path for package changes done for Apertis 83 since they can go directly into the main upstream distribution 84 - Debian stable and security updates tend to be more conservative and 85 stable making it easier to track over time 86 Debian provides a backports repository for packages where a version 87 newer than that in the stable release might be of interest 88 Risks 89 Debian does not use a strict 2-years release cycle. Thus the Apertis 90 platform update cycle also cannot be strictly time-based when using 91 Debian 92 Ubuntu 18.04 93 • Benefits 94 - Ubuntu has a strict time-based release cycle of a new LTS every two 95 years 96 Ubuntu also has a 6-months regular release cycle (with very limited 97 support) should the decision to use LTS version be revised 98 Risks qq - Ubuntu is bound to the health, technical and commercial strategy 100 of Canonical. Canonical has shifted its focus several times in recent 101 years which has resulted in numerous changes not aligned to the 102 goals of Apertis. Canonical has also introduced their own technolo-103 gies rather than utilising 'upstream' technologies a number of times, 104 for example Mir vs. Wayland and Snappy vs. Flatpak. Some of

extra support effort

these choices have had an impact when utilising Ubuntu packages in

Apertis, requiring extra work to be performed (e.g. disabling Mir).

packages, which can destabilise things for Apertis as well as requiring

Ubuntu's main support is around a subset of Debian packages avail-

able in the Ubuntu's *main* repository. A more complete set of pack-

ages can be found in Ubuntu's Universe respositories, however these

## <sup>118</sup> Impact of move

128

129

137

138

## <sup>119</sup> Will the rebase process take longer if we move to Debian <sup>120</sup> instead of the next Ubuntu LTS release?

<sup>121</sup> When Apertis tracked non-LTS Ubuntu releases, rebases were performed every <sup>122</sup> six months following each release. Every rebase took about two months to <sup>123</sup> complete. As a part of a rebase procedure, the following tasks needed to be <sup>124</sup> completed:

- Fork Apertis in preparation of a new release
- Set up Merge-our-Misc to track the latest Ubuntu release
- Repeat until there are no build failures:
  - Accept automatic merges produced Merge-our-Misc
  - If there are no automatic merges, process pending manual merges
- If new packages break the builds, fix them

Since Apertis no longer pulls changes from regular Ubuntu releases, it is quite
behind the future release which is set to be an LTS. The delta between Apertis
and the current Ubuntu is about the same size as between Apertis and Debian,
and will take similar time to process. Regardless of the decision to stay with
Ubuntu or move to Debian, the following work will need to be done:

- Switch to the latest versions of GCC and rebuild all packages with them
  - Rebase all packages to their newer versions from either Ubuntu 18.03 or
  - Debian stretch, for each component
- Review Apertis changes to the packages updated upstream, potentially
   dropping them if they are no longer relevant
- Switch to the latest Java version for the SDK, dropping Apertis patches fixing build failures with the older Java version Apertis shipped

According to our estimation, the difference in the amount of time needed to perform that work is going to be negligible.

## <sup>145</sup> Ubuntu does validation, this would be missing if we move <sup>146</sup> to Debian?

We understand that Ubuntu does some hardware validation testing of standard
Ubuntu configurations (which we do not use) against hardware from their partners who pay for it (https://certification.ubuntu.com/). The vast majority of
the functionality that such tests will focus on are related to kernel functionality.
Since we do not for the most part use the Ubuntu kernel and target different

hardware, these tests do not seem relevant in our use case and thus we do not
lose anything by moving to Debian.

### <sup>154</sup> Do we lose anything by moving to Debian?

We believe that we do not lose anything other than the strict time-based release cycle by moving from Ubuntu to Debian. However, we feel that this is now less important given we are now syncing on just Ubuntu LTS releases (every 2 years), and with Debian release cycle tending to a 2 year release cycle this is not believed to be problematic.

## 160 **Recommendations**

Collabora recommends rebasing on Debian Stretch for Apertis 18.06 and on-161 wards. Most of the benefits of basing on Ubuntu have gone away since the 162 original decision was taken in late 2011, while the projects dynamics have also 163 changed to better suit a Debian based distribution. Basing on Debian rather 164 than Ubuntu, would move Apertis closer to it's ultimate upstream (as Ubuntu 165 is also a downstream of Debian) cutting out a middle-man, which currently 166 brings very little to the table as described above. This also may make the pro-167 cess of upstreaming appropriate package changes more efficient, reducing the 168 maintenance overhead in Apertis. 169
