92	Appendix: W3C API	43

93 This documents possible approaches to designing an API for exposing vehicle
 94 sensor information and allowing interaction with actuators to application bun-
 95 dles on an Apertis system.

96 The major considerations with a sensors and actuators API are:

- 97 • Bandwidth and latency of sensor data such as that from parking cameras
- 98 • Enumeration of sensors and actuators
- 99 • Support for multiple vehicles or accessories
- 100 • Support for third-party and OEM accessories and customisations
- 101 • Multiplexing of access to sensors
- 102 • Privilege separation between application bundles using the API
- 103 • Policy to restrict access to sensors (privacy sensitive)
- 104 • Policy to restrict access to actuators (safety critical)

105 Terminology and concepts

106 Vehicle

107 For the purposes of this document, a *vehicle* may be a car, car trailer, motorbike,
 108 bus, truck tractor, truck trailer, agricultural tractor, or agricultural trailer,
 109 amongst other things.

110 Intra-vehicle network

111 The *intra-vehicle network* connects the various devices and processors through-
 112 out a vehicle. This is typically a CAN or LIN network, or a hierarchy of such
 113 networks. It may, however, be based on Ethernet or other protocols.

114 The vehicle network is defined by the OEM, and is statically defined — all de-
 115 vices which are supported by the network have messages or bandwidth allocated
 116 for them at the time of manufacture. No devices which are not known at the
 117 time of manufacture can be supported by the vehicle network.

118 Inter-vehicle network

119 An *inter-vehicle network* connects two or more *physically connected* vehicles
 120 together for the purposes of exchanging information. For example, a network
 121 between a truck tractor and trailer.

122 An inter-vehicle network (for the purposes of this document) does *not* cover
 123 transient communications between separate cars on a motorway, for example;
 124 or between a vehicle and static roadside infrastructure it passes. These are

125 car-to-car (C2C) and car-to-infrastructure (C2X) communications, respectively,
126 and are handled separately.

127 **Sensor**

128 A *sensor* is any input device which is connected to the vehicle's network but
129 which is not a direct part of the dashboard user interface. For example: parking
130 cameras, ultrasonic distance sensors, air conditioning thermometers, light level
131 sensors, etc.

132 **Actuator**

133 An *actuator* is any output device which is connected to the vehicle's network
134 but which is not a direct part of the dashboard user interface. For example:
135 air conditioning heater, door locks, electric window motors, interior lights, seat
136 height motors, etc.

137 **Device**

138 A sensor or actuator.

139 **Use cases**

140 A variety of use cases for application bundle usage of sensor data are given
141 below. Particularly important discussion points are highlighted at the bottom
142 of each use case.

143 **Augmented reality parking**

144 When parking, the feed from a rear-view camera should be displayed on the
145 screen, with an overlay showing the distance between the back of the vehicle
146 and the nearest object, taken from ultrasonic or radar distance sensors.

147 The information from the sensors has to be synchronised with the camera, so
148 correct distance values are shown for each frame. The latency of the output
149 image has to be low enough to not be noticed by the driver when parking at
150 low speeds (for example, 5km·h).

151 **Virtual mechanic**

152 Provide vehicle status information such as tyre pressure, engine oil level, washer
153 fluid level and battery status in an application bundle which could, for example,
154 suggest routine maintenance tasks which need to be performed on the vehicle.

155 (Taken from [http://www.w3.org/2014/automotive/vehicle_spec.html#h2_](http://www.w3.org/2014/automotive/vehicle_spec.html#h2_abstract)
156 [abstract](http://www.w3.org/2014/automotive/vehicle_spec.html#h2_abstract).)

157 **Trailer**

158 The driver attaches a trailer to their vehicle and it contains tyre pressure sensors.
159 These should be available to the virtual mechanic bundle.

160 **Petrol station finder**

161 Monitor the vehicle's fuel level. When it starts to get low, find nearby petrol
162 stations and notify the driver if they are near one. Note that this requires
163 programs to be notified of fuel level changes while not in the foreground.

164 **Sightseeing application bundle**

165 An application bundle could highlight sights of interest out of the windows by
166 combining the current location (from GPS) with a direction from a compass
167 sensor. Using a compass rather than the GPS' velocity angle allows the bundle
168 to work even when the vehicle is stationary.

169 **Privacy concern:** Any application bundle which has access to compass data
170 can potentially use dead reckoning to track the vehicle's location, even without
171 access to GPS data.

172 **Basic model vehicle**

173 If a vehicle does not have a compass sensor, the sightseeing bundle cannot
174 function at all, and the Apertis store should not allow the user to install it on
175 their vehicle.

176 **Changing bundle functionality when driving at speed**

177 An application bundle may want to voluntarily change or disable some of its
178 features when the vehicle is being driven (as opposed to parked), or when it
179 is being driven fast (above a cut-off speed). It might want to do this to avoid
180 distracting the driver, or because the features do not make sense when the
181 vehicle is moving. This requires bundles to be able to access speedometer and
182 driving mode information.

183 If the application bundle is using a cut-off speed for this decision, it should not
184 have to continually monitor the vehicle's speed to determine whether the cut-off
185 has been reached.

186 **Changing audio volume with vehicle or cabin noise**

187 Bundles may want to adjust their audio output volume, or disable audio output
188 entirely, in response to changes in the vehicle's cabin or engine noise levels. For
189 example, a game bundle could reduce its effects volume if a loud conversation
190 can be heard in the cabin; but it might want to increase its effects volume if
191 engine noise increases.

192 **Privacy concern:** This should be implemented by granting access to overall
193 ‘volume level’ information for different zones in the vehicle; but *not* by grant-
194 ing access to the actual audio input data, which would allow the bundle to
195 record conversations. The overall volume level information should be sufficiently
196 smoothed or high-latency that a malicious application cannot infer audio infor-
197 mation from it.

198 **Night mode**

199 Programs may wish to change their colour scheme according to the ambient
200 lighting level in a particular zone in the cabin, for example by switching to a
201 ‘night mode’ with a dark colour scheme if driving at night, but not if an interior
202 light is on. This requires bundles to be able to read external light sensors and
203 the state of internal lights.

204 **Weather feedback or traffic jam feedback**

205 A weather bundle may want to crowd-source information about local weather
206 conditions to corroborate its weather reports. Information from external rain,
207 temperature and atmospheric pressure sensors could be collected at regular
208 intervals – even while the weather bundle is not active – and submitted to
209 an online weather service as network connectivity permits.

210 Similarly, a traffic jam or navigation bundle may want to crowd-source informa-
211 tion about traffic jams, taking input from the speedometer and vehicle separa-
212 tion distance sensors to report to an online service about the average speed and
213 vehicle separation in a traffic jam.

214 **Insurance bundle**

215 A vehicle insurance company may want to offer lower insurance premiums to
216 drivers who install its bundle, if the bundle can record information about their
217 driving safety and submit it to the insurance company to give them more infor-
218 mation about the driver’s riskiness. This would need information such as driving
219 duration, distances driven, weather conditions, acceleration, braking frequency,
220 frequency of using indicator lights, pitch, yaw and roll when cornering, and
221 potentially vehicle maintenance information. It would also require access to
222 unique identifiers for the vehicle, such as its VIN. The data would need to be
223 collected regardless of whether the vehicle is connected to the internet at the
224 time — so it may need to be stored for upload later.

225 **Privacy concern:** Unique identification information like a VIN should not be
226 given to untrusted bundles, as they may use it to track the user or vehicle.

227 **Driving setup bundle**

228 An application bundle may want to control the driving setup — the position of
229 the steering wheel, its rake, the position of the wing mirrors, the seat position

230 and shape, whether the vehicle is in sport mode, etc. If a guest driver starts using
231 the vehicle, they could import their settings from the same bundle on their own
232 vehicle, and the bundle would automatically adjust the physical driving setup
233 in the vehicle to match the user's preferences. The bundle may want to restrict
234 these changes to only happen while the vehicle is parked.

235 **Odour detection**

236 A vehicle manufacturer may have invented a new type of interior sensor which
237 can detect foul odours in the cabin. They want to integrate this into an ap-
238 plication bundle which will change the air conditioning settings temporarily to
239 clear the odour when detected. The Sensors and Actuators API currently has
240 no support for this new sensor. The manufacturer does not expect their bundle
241 to be used in other vehicles.

242 **Air conditioning control**

243 An application bundle which connects to wrist watch body monitors on each
244 of the passengers (through an out-of-band channel like Bluetooth, which is out
245 of the scope of this document; see [Bluetooth wrist watch and the Internet of](#)
246 [Things](#) may want to change the cabin temperature in response to thermometer
247 readings from passengers' watches.

248 **Automatic window feedback**

249 In order to do this, the bundle may also need to close the automatic windows,
250 but one of the passengers has their arm hanging out of the window and the
251 hardware interlock prevents it closing. The bundle must handle being unable
252 to close the window.

253 **Agricultural vehicle**

254 Apertis is used by an agricultural manufacturer to provide an IVI system for
255 drivers to use in their latest tractor model. The manufacturer provides a pre-
256 installed app for controlling their own brand of agricultural accessories for the
257 tractor, so the driver can use it to (for example) control a tipping trailer and
258 a baler which are hitched to each other behind the tractor, and also control a
259 bale spear attached to the front of the tractor.

260 **Roof box**

261 A car driver adds a roof box to their car, provided by a third party, containing
262 a safety sensor which detects when the box is open. The built-in application
263 bundle for alerting the driver to doors which are open when the vehicle starts
264 moving should be able to detect and use this sensor to additionally alert the
265 driver if the roof box is open when they start moving.

266 **Truck installations**

267 Trucks are sold as a basis ‘vanilla’ truck with a special installation on top,
268 which is customised for the truck’s intended use. For example, a rubbish truck,
269 tipping truck or police truck. The installation is provided by a third party
270 who has a relationship with the basis truck manufacturer. Each installation
271 has specific sensors and actuators, which are to be controlled by an application
272 bundle provided by the third party or by the manufacturer.

273 **Compromised application bundle**

274 An application bundle on the system, A, is installed with permissions to adjust
275 the driver’s seat position, which is one of the features of the bundle. Another
276 application bundle, B, is installed without such permissions (as they are not
277 needed for its normal functionality).

278 **Safety critical:** An attacker manages to exploit bundle B and execute arbitrary
279 code with its privileges. The attacker must not be able to escalate this exploit
280 to give B permission to use actuators attached to the system, or extra sensors.
281 Similarly, they must not be able to escalate the exploit to gain the privileges of
282 bundle A, and hence bundle A’s permissions to adjust the driver’s seat position.

283 **Ethernet intra-vehicle network**

284 A vehicle manufacturer wants to support high-bandwidth devices on their intra-
285 vehicle network, and decides to use Ethernet for all intra-vehicle communica-
286 tions, instead of a more traditional CAN or LIN network. Their use of a differ-
287 ent network technology should not affect enumeration or functionality of devices
288 as seen by the user.

289 **Development against the SDK**

290 An application developer wants to use a local gyroscope sensor attached to their
291 development machine to feed input to their application while they are developing
292 and testing it using the SDK.

293 **Non-use-cases**

294 **Bluetooth wrist watch and the Internet of Things**

295 A passenger gets into the vehicle with a Bluetooth wrist watch which monitors
296 their heart rate and various other biological variables. They launch their health
297 monitor bundle on the IVI display, and it connects to their watch to download
298 their recent activity data.

299 This is not a use case for the Sensors and Actuators API; it should be handled
300 by direct Bluetooth communication between the health monitor bundle and the
301 watch. If the Sensors and Actuators API were to support third-party devices

302 (as opposed to ones specified and installed by the vehicle manufacturer or sup-
303 pliers), having full support for all available devices would become a lot harder.
304 Additionally, devices would then appear and disappear while the vehicle was
305 running (for example, if the user turned off their watch’s Bluetooth connection
306 while driving); this is not possible with fixed in- vehicle sensors, and would
307 complicate the sensor enumeration API.

308 More generally, this use-case is a specific case of the internet of things (IoT),
309 which is out of scope for this design for the reasons given above. Additionally,
310 supporting IoT devices would mean supporting wireless communications as part
311 of the sensors service, which would significantly increase its attack surface due
312 to the complexity of wireless communications, and the fact they enable remote
313 attacks.

314 **Car-to-car and car-to-infrastructure communications**

315 In C2C and C2X communications, vehicles share data with each other as they
316 move into range of each other or static roadside infrastructure. This information
317 may be anything from braking and acceleration information shared between
318 convoys of vehicles to improve fuel efficiency, to payment details shared from a
319 car to toll booth infrastructure.

320 While many of the use cases of C2C and C2X cover sharing of sensor data, the
321 data being shared is typically a limited subset of what’s available on one vehi-
322 cle’s network. Due to the dynamic nature of C2C and C2X networks, and the
323 greater attack surface caused by the use of more complex technologies (radio
324 communications rather than wired buses), a conservative approach to security
325 suggests implementing C2C and C2X on a use-case-by-use-case basis, using sep-
326 arate system components to those handling intra-vehicle sensors and actuators.
327 This ensures that control over actuators, which is safety critical, remains in a
328 separate security domain from C2C and C2X, which must not have access to
329 actuators on the local vehicle. See [Security](#).

330 An initial suggestion for C2C and C2X communications would be to implement
331 them as a separate service which consumes sensor data from the sensors and
332 actuators service just like other applications.

333 **Buddied and vehicle fleet communications**

334 Similarly, long-range communications of sensor data between buddied vehicles
335 or vehicles operating in a fleet (for example, a haulage or taxi fleet) should
336 be handled separately from the sensors and actuators service, as such systems
337 involve network communications. Typical use cases here would be reporting
338 speed and fuel usage information from trucks or taxis back to headquarters; or
339 letting two friends know each others’ locations and traffic conditions when both
340 doing the same journey.

341 Requirements

342 Enumeration of devices

343 An application bundle must be able to enumerate devices in the vehicle, includ-
344 ing information about where they are located in the vehicle (for example, so
345 that it can adjust the position and setup of the driver’s seat but not others (see
346 [Driving setup bundle](#))).

347 It is expected that the set of devices in a vehicle may change dynamically while
348 the vehicle is running, for example if a roof box were added while the engine
349 was running ([Roof box](#)).

350 Enumeration is particularly important for bundles, as the set of sensors in a
351 particular vehicle will not change, but the set of sensors seen by a bundle across
352 all the vehicles it’s installed in will vary significantly.

353 Enumeration of vehicles

354 An application bundle must be able to enumerate vehicles connected to the
355 inter-vehicle network, for example to discover the existence of hitched trailers
356 or agricultural vehicles ([Trailer](#), [Agricultural vehicle](#)).

357 It is expected that the set of vehicles may change dynamically while the vehicles
358 are running.

359 Retrieving data from sensors

360 An application bundle must be able to retrieve data from sensors. This data
361 must be strongly typed in order to minimise the possibility of a bundle mis-
362 interpreting it, or sensors from different manufacturers using different units,
363 for example. Sensor data could vary in type from booleans (see [Night mode](#))
364 through to streaming video data (see [Augmented reality parking](#)). Sensor data
365 may be processed by the system to make it more useful for application bundles;
366 they do not need direct access to raw sensor data.

367 Sending data to actuators

368 An application bundle must be able to send data to actuators (including invok-
369 ing methods on them). This data must be strongly typed in order to minimise
370 the possibility of a bundle misinterpreting it, or actuators from different man-
371 ufacturers using different units, for example. Actuator data could vary in type
372 from booleans through to enumerated types (see [Driving setup bundle](#)) and
373 possibly larger data streams, though no concrete use cases exist for that.

374 Network independence

375 The API should be independent of the network used to connect to devices —
376 whether it be Ethernet, LIN or CAN; or whether the device is connected directly

377 to a host processor ([Ethernet intra-vehicle network](#)).

378 **Bounded latency of processing sensor data**

379 Certain sensor data has bounds on its latency. For example, pitch, yaw and
380 roll information typically arrive as angular rate from sensors, and have to be
381 integrated over time to be useful to application bundles — if sensor readings
382 are missed, accuracy decreases. Sensor readings should be processed within the
383 latency limits specified by the sensors. The limits on forwarding this processed
384 data to bundles are less strict, though it is expected to be within the latency
385 noticeable by humans (around 20ms) so that it can be displayed in real time
386 (see [Augmented reality parking](#), [Sightseeing application bundle](#), [Changing audio
387 volume with vehicle or cabin noise](#)).

388 **Extensibility for OEMs**

389 New types of device may be developed after the Sensors and Actuators API is
390 released. As the set of sensors in a vehicle does not vary after release, already-
391 deployed versions of the API do not need to handle unknown devices. However,
392 there must be a mechanism for OEMs or third parties working with them to
393 define new device types when developing a new vehicle or an installation or
394 accessory to go with it. In order for new devices to be usable by non-OEM
395 application bundle authors, the Sensors and Actuators API must be updatable
396 or extensible to support them. ([Odour detection](#), [Truck installations](#).)

397 **Third-party backends**

398 If an OEM or third party produces a new device which can be connected to
399 an existing vehicle, some code needs to exist to allow communication between
400 the device and the Apertis sensors and actuators service. This code must be
401 written by the device manufacturer, as they know the hardware, and must be
402 installable on the Apertis system before or after vehicle production (so as a
403 system or non-system application). (See [Agricultural vehicle](#), [Roof box](#), [Truck
404 installations](#).)

405 **Third-party backend validation**

406 If a third-party device is exposed to the sensors and actuators service, the third
407 party might not be one who has contributed to or used Apertis before. There
408 must be a process for validating backends for the sensors and actuators system,
409 to ensure they have a certain level of code quality and security, in order to
410 reduce the attack surface of the service as a whole. (See [Roof box](#).)

411 **Notifications of changes to sensor data**

412 All sensor data changes over time, so the API must support notifying application
413 bundles of changes to sensor data they are interested in, without requiring the

414 bundle to poll for updates (see [Petrol station finder](#), [Sightseeing application](#)
415 [bundle](#), [Changing bundle functionality when driving at speed](#), [Changing audio](#)
416 [volume with vehicle or cabin noise](#), [Night mode](#), [Odour detection](#)).

417 Application bundles should be able to request notifications only when a sensor
418 value crosses a given threshold, to avoid unnecessary notifications (see [Changing](#)
419 [bundle functionality when driving at speed](#)).

420 **Uncertainty bounds**

421 Sensors are not perfectly accurate, and additionally a sensor's accuracy may
422 vary over time; each sensor measurement should be provided with uncertainty
423 bounds. For example, the accuracy of geolocation by mobile phone tower varies
424 with your location.

425 This is especially possible with data aggregated from multiple sensors, where
426 the aggregate accuracy can be statistically modelled (for example, distance cal-
427 culation from multiple sensors in [Weather feedback or traffic jam feedback](#)).

428 **Failure feedback**

429 As actuators are physical devices, they can fail. The API cannot assume au-
430 tomatic, immediate or successful application of its changes to properties, and
431 needs to allow for feedback on all property changes.

432 For example, the air conditioning coolant on an older vehicle might have leaked,
433 leaving the air conditioning system unable to cool the cabin effectively. Appli-
434 cation bundles which wish to set the temperature need to have feedback from a
435 thermometer to work out whether the temperature has reached the target value
436 (see [Air conditioning control](#)).

437 Another example is failure to close windows: [Automatic window feedback](#).

438 **Timestamping**

439 In-vehicle networks (especially Ethernet) may have variable latency. In order
440 to correlate measurements from multiple sensors on the end of connections of
441 varying latency, each measurement should have an associated timestamp, added
442 at the time the measurement was recorded (see [Augmented reality parking](#),
443 [Sightseeing application bundle](#)).

444 **Triggering bundle activation**

445 Various use cases require a bundle to be able to trigger actions based on sensor
446 data reaching a certain value, even if the program is not running at that time
447 (see [Petrol station finder](#), [Changing audio volume with vehicle or cabin noise](#),
448 [Odour detection](#)). This requires some operating system service to monitor a
449 list of trigger conditions even while the programs which set those triggers are

450 not running, and start the appropriate program so that it can respond to that
451 trigger.

452 **Bulk recording of sensor data**

453 Some bundles require to be able to regularly record sensor measurements, with
454 the intention of processing them (for example, uploading them to an online
455 service) at a later time (see [Weather feedback or traffic jam feedback](#), [Insurance
456 bundle](#)). This is not latency sensitive. As an optimisation, a system service
457 could record the sensor readings for them, to avoid waking up the programs
458 regularly.

459 Data recorded in this way must only be accessible to the application bundle
460 which requested it be recorded.

461 The requesting application bundle is responsible for processing the data period-
462 ically, and deleting it once processed. The system must be able to periodically
463 overwrite recorded data if running low on space.

464 **Sensor security**

465 As highlighted by the privacy concerns in several of the use cases ([Sightseeing
466 application bundle](#), [Changing audio volume with vehicle or cabin noise](#), [Insur-
467 ance bundle](#)), there are security concerns with allowing bundles access to sensor
468 data. The system must be able to restrict access to some or all types of sensor
469 data unless the user has explicitly granted a bundle access to it. Bundles with
470 access to sensor data must be in separate security domains to prevent privilege
471 escalation ([Compromised application bundle](#)).

472 **Actuator security**

473 Control of actuators is safety critical but not privacy sensitive (unlike sensors).
474 The system must be able to restrict write access to some or all types of actuator
475 unless the user has explicitly granted a bundle access to it. Bundles with access
476 to actuators must be in separate security domains to prevent privilege escalation
477 ([Compromised application bundle](#)).

478 **App store knowledge of device requirements**

479 The Apertis store must know which devices (sensors *and* actuators) an appli-
480 cation bundle requires to function, and should not allow the user to install a
481 bundle which requires a device their vehicle does not have, or the bundle would
482 be useless ([Basic model vehicle](#)).

483 **Accessing devices on multiple vehicles**

484 The API must support accessing properties for multiple vehicles, such as hitched
485 agricultural trailers ([Agricultural vehicle](#)) or car trailers ([Trailer](#)). These vehi-

cles may appear dynamically while the IVI system is running; for example, in the case where the driver hitches a trailer with the engine running.

Note: This requirement explicitly does not support C2C or C2X, which are out of scope of this document. (See [Car-to-car and car-to-infrastructure communications](#)).

Third-party accessories

The API must support accessing properties of third-party accessories — either dynamically attached to the vehicle ([Roof box](#)) or installed during manufacture ([Truck installations](#)).

SDK hardware support

The SDK must contain a backend for the system which allows appropriate hardware which is attached to the developer’s machine to be used as sensors or actuators for development and testing of applications (see [Development against the SDK](#)).

This backend must not be available in target images.

Background on intra-vehicle networks

For the purposes of informing the interface design between the Sensors and Actuators API and the underlying intra-vehicle network, some background information is needed on typical characteristics of intra-vehicle networks.

CAN and LIN are common protocols in use, though future development may favour Ethernet or other protocols. In all cases, the OEM statically defines all protocols, data structures, and devices which can be on the network. Bandwidth is allocated for all devices at the time of manufacture; even for devices which are only optionally connected to the network, either because they’re a premium vehicle feature, or because they are detachable, such as trailers. In these cases, data structures on the network relating to those devices are empty when the devices are not connected.

Sometimes flags are used in the protocol, such as ‘is a trailer connected?’.

There are no common libraries for accessing vehicle networks: they differ between OEMs.

Existing sensor systems

This chapter describes the approaches taken by various existing systems for exposing sensor information to application bundles, because it might be useful input for Apertis’ decision making. Where available, it also provides some details of the implementations of features that seem particularly interesting or relevant.

522 **W3C Vehicle Information Service Specification (VISS)**

523 The W3C [Vehicle Information Service Specification](https://www.w3.org/TR/vehicle-information-service/)¹ defines a WebSocket based
524 API for a Vehicle Information Service (VIS) to enable client applications to
525 get, set, subscribe and unsubscribe to vehicle signals and data attributes. This
526 specification defines a number of methods for accessing vehicle data which are
527 strictly agnostic to the data model [Vehicle Signal Specification](https://github.com/GENIVI/vehicle_signal_specification)².

528 The Vehicle Signal Specification (VSS) focuses on vehicle signals, in the sense
529 of classical sensors and actuators with the raw data communicated over vehicle
530 buses and data which is more commonly associated with the infotainment system
531 alike. This defines a ‘tree-like’ logical taxonomy of the vehicle, (formally a
532 Directed Acyclic Graph), where major vehicle structures (e.g. body, engine)
533 are near the top of the tree and the logical assemblies and components that
534 comprise them, are defined as their child nodes.

535 The VSS supports both extensibility and the ability to define private branches.

536 **GENIVI Web API Vehicle**

537 The GENIVI [Web API Vehicle](http://git.projects.genivi.org/?p=web-api-vehicle.git;a=blob_plain;f=doc/WebAPIforVehicleDataRI.pdf;hb=HEAD)³ (sic) is a proof of concept API for exposing and
538 manipulating vehicle information to GENIVI apps via a JavaScript API. It is
539 very similar to the W3C Vehicle Information Access API, and seems to expose
540 a very similar set of properties.

541 The [Web API Vehicle](http://git.projects.genivi.org/?p=web-api-vehicle.git;a=blob_plain;f=doc/WebAPIforVehicleDataRI.pdf;hb=HEAD)⁴ is a proxy for exposing a separate Vehicle Interface API
542 within a HTML5 engine. The Vehicle Interface API itself is apparently a D-Bus
543 API for sharing vehicle information between the CAN bus and various clients,
544 including this Web API Vehicle and any native apps. Unfortunately, the Vehicle
545 Interface API seems to be unspecified as of August 2015, at least in publicly
546 released GENIVI documents.

547 [http://git.projects.genivi.org/?p=web-api-vehicle.git;a=blob_
548 plain;f=doc/WebAPIforVehicleDataRI.pdf;hb=HEAD](http://git.projects.genivi.org/?p=web-api-vehicle.git;a=blob_plain;f=doc/WebAPIforVehicleDataRI.pdf;hb=HEAD) Section
549 2.2.3

550 The Web API Vehicle has the same features and scope as the W3C API, but its
551 implementation is clumsier, relying a lot more on seemingly unstructured magic
552 strings for accessing vehicle properties.

553 [http://git.projects.genivi.org/?p=web-api-vehicle.git;a=blob_
554 plain;f=doc/WebAPIforVehicleDataRI.pdf;hb=HEAD](http://git.projects.genivi.org/?p=web-api-vehicle.git;a=blob_plain;f=doc/WebAPIforVehicleDataRI.pdf;hb=HEAD)

¹<https://www.w3.org/TR/vehicle-information-service/>

²https://github.com/GENIVI/vehicle_signal_specification

³[http://git.projects.genivi.org/?p=web-api-vehicle.git;a=blob_plain;f=doc/
WebAPIforVehicleDataRI.pdf;hb=HEAD](http://git.projects.genivi.org/?p=web-api-vehicle.git;a=blob_plain;f=doc/WebAPIforVehicleDataRI.pdf;hb=HEAD)

⁴[http://git.projects.genivi.org/?p=web-api-vehicle.git;a=blob_plain;f=doc/
WebAPIforVehicleDataRI.pdf;hb=HEAD](http://git.projects.genivi.org/?p=web-api-vehicle.git;a=blob_plain;f=doc/WebAPIforVehicleDataRI.pdf;hb=HEAD)

555 It was last publicly modified in May 2013, and might not be under development
556 any more. Furthermore, a lot of the wiki links in the specification link to private
557 and inaccessible data on collab.genivi.org.

558 **Apple HomeKit**

559 [Apple HomeKit](#)⁵ is an API to allow apps on Apple devices to interact with
560 sensors and actuators in a home environment, such as garage doors, thermostats,
561 thermometers and light switches, amongst others. It is designed explicitly for the
562 home environment, and does not consider vehicles. However, as it is effectively
563 an API for allowing interactions between sandboxed apps and external sensors
564 and actuators, it bears relevance to the design of such an API for vehicles.

565 At its core, HomeKit allows enumeration of devices (‘accessories’) in a home.
566 A large part of its API is dedicated to grouping these into homes, rooms, ser-
567 vice groups and zones so that collections of accessories can be interacted with
568 simultaneously.

569 Each accessory implements one or more ‘services’ which are defined interfaces
570 for specific functionality, such as a light switch interface, or a thermostat inter-
571 face. Each service can expose one or more ‘characteristics’ which are readable
572 or writeable properties of that interface, such as whether a light is on, the cur-
573 rent temperature measured by a thermostat, or the target temperature for the
574 thermostat.

575 It explicitly maintains separation between *current* and *target* states for certain
576 characteristics, such as temperature controlled by a thermostat, acknowledging
577 that changes to physical systems take time.

578 A second part of the API implements ‘actions’ based on sensor values, which are
579 arbitrary pieces of code executed when a certain condition is met. Typically,
580 this would be to set the value of a characteristic on some actuator when the
581 input from another sensor meets a given condition. For example, switching on a
582 group of lights when the garage door state changes to ‘open’ as someone arrives
583 in the garage.

584 Critically, triggers and actions are handled by the iOS operating system, so are
585 still checked and executed when the app which created them is not active.

586 HomeKit has a [simulator](#)⁶ for developing apps against.

⁵<https://developer.apple.com/homekit/>

⁶https://developer.apple.com/library/ios/documentation/NetworkingInternet/Conceptual/HomeKitDeveloperGuide/TestingYourHomeKitApp/TestingYourHomeKitApp.html#//apple_ref/doc/uid/TP40015050-CH7-SW1

587 **Apple External Accessory API**

588 As a precursor to HomeKit, Apple also supports an [External Accessory API](#)⁷,
589 which allows any iOS device to interact with accessories attached to the device
590 (for example, through Bluetooth).

591 In order to use the External Accessory API, an app must list the accessory
592 protocols it supports in its app manifest. Each accessory supports one or more
593 protocols, defined by the manufacturer, which are interfaces for aspects of the
594 device's functionality. They are equivalent to the 'services' in the HomeKit API.
595 The code to implement these protocols is provided by the manufacturer, and
596 the protocols may be proprietary or standard.

597 Each accessory exposes [versioning information](#)⁸ which can be used to determine
598 the protocol to use.

599 All communication with accessories is done via [sessions](#)⁹, rather than one-shot
600 reads or writes of properties. Each session is a bi-directional stream along which
601 the accessory's protocol is transmitted.

602 **iOS CarPlay**

603 iOS [CarPlay](#)¹⁰ is a system for connecting an iOS device to a car's IVI system,
604 displaying apps from the phone on the car's display and allowing those apps to
605 be controlled by the car's touchscreen or physical controls. It *does not give*¹¹
606 the iOS device access to car sensor data, and hence is not especially relevant to
607 this design.

608 It *does not*¹² (as of August 2015) have an API for integrating apps with the IVI
609 display.

610 Most vehicle manufacturers have pledged support for it in the coming years.

611 **Android Auto**

612 [Android Auto](#)¹³ is very similar to iOS CarPlay: a system for connecting a phone
613 to the vehicle's IVI system so it can use the display and touchscreen or physical
614 controls. As with CarPlay, it *does not* give the Android device access to vehicle
615 sensor data, although (as of August 2015) that is planned for the future.

⁷<https://developer.apple.com/library/ios/featuredarticles/ExternalAccessoryPT/Introduction/Introduction.html>

⁸https://developer.apple.com/library/ios/documentation/ExternalAccessory/Reference/EAAccessory_class/index.html#//apple_ref/occ/instp/EAAccessory/modelNumber

⁹https://developer.apple.com/library/ios/documentation/ExternalAccessory/Reference/EASession_class/index.html#//apple_ref/occ/instp/EASession/accessory

¹⁰<http://www.apple.com/uk/ios/carplay/>

¹¹<http://www.tomsguide.com/us/apple-carplay-faq,news-18450.html>

¹²<https://developer.apple.com/carplay/>

¹³<https://www.android.com/auto/>

616 As of August 2015, it [has an API for apps](#)¹⁴, allowing audio and messaging apps
617 to improve their integration with the IVI display.

618 Most vehicle manufacturers have pledged support for it in the coming years.

619 **MirrorLink**

620 [MirrorLink](#)¹⁵ is a proprietary system for integrating phones with the IVI display
621 — it is similar to iOS CarPlay and Android Auto, but produced by the [Car](#)
622 [Connectivity Consortium](#)¹⁶ rather than a device manufacturer like Apple or
623 Google.

624 The specifications for MirrorLink are proprietary and only available to registered
625 developers. In [their brochure](#)¹⁷ (page 2), it is stated that support for allowing
626 apps access to sensor data is planned for the future (as of 2014).

627 MirrorLink is apparently the technology behind Microsoft's [Windows in the](#)
628 [Car](#)¹⁸ system, which was announced in April 2014.

629 **Android Sensor API**

630 [Android's Sensor API](#)¹⁹ is a mature system for accessing mobile phone sensors.
631 There are a more constrained set of sensors available in phones than in vehi-
632 cles, hence the API exposes individual sensors, each implementing an interface
633 specific to its type of sensor (for example, accelerometer, orientation sensor or
634 pressure sensor). The API places a lot of emphasis on the physical limitations of
635 each sensor, such as its range, resolution, and uncertainty of its measurements.

636 The sensors required by an app are listed in its manifest file, which allows the
637 Google Play store to filter apps by whether the user's phone has all the necessary
638 sensors.

639 As Android runs on a multitude of devices from different manufacturers, each
640 with different sensors, enumeration of the available sensors is also an emphasis
641 of the API, using its [SensorManager](#)²⁰ class.

642 [Sensors](#)²¹ can be queried by apps, or apps can register for notifications when
643 sensor values change, including when the app is not in the foreground or when

¹⁴<https://developer.android.com/training/auto/index.html>

¹⁹<http://developer.android.com/guide/topics/sensors/index.html>

²⁰<http://developer.android.com/reference/android/hardware/SensorManager.html>

²¹<http://developer.android.com/reference/android/hardware/SensorManager.html#registerListener%28android.hardware.SensorEventListener,%20android.hardware.Sensor,%20int%29>

644 the device is asleep (if supported by the sensor). Apps can also [register](#)²² for no-
645 tifications when sensor values satisfy some trigger, such as a ‘significant’ change.

646 **Automotive Message Broker**

647 [Automotive Message Broker](#)²³ is an Intel OTC project to broker information
648 from the vehicle networks to applications, exposing a [tweaked version](#)²⁴ of the
649 W3C Vehicle Information Access API (with a few types and naming conventions
650 tweaked) over D-Bus to apps, and interfacing with whatever underlying networks
651 are in use in the vehicle. In short, it has the same goals as the Apertis Sensors
652 and Actuators API.

653 As of August 2015, it was last modified in June 2015, so is an active project
654 (although Tizen is in decline, so this may change). Although it is written in
655 C++, it uses GNOME technologies like GObject Introspection; but it also uses
656 Qt. Its main daemon is the Automotive Message Broker daemon, ambd.

657 One area where it differs from the Apertis design is [Security](#); it does not im-
658 plement the polkit integration which is key to the vehicle device daemon secu-
659 rity domain boundary. Modifying the security architecture of a large software
660 project after its initial implementation is typically hard to get right.

661 Another area where ambd differs from the Apertis design is in the backend:
662 ambd uses multiple plugins to aggregate vehicle properties from many places.
663 Apertis plans to use a single OEM-provided, vehicle-specific plugin.

664 **AllJoyn**

665 The [AllJoyn Framework](#)²⁵ is an internet of things (IoT) framework produced
666 under the Linux Foundation banner and the [AllSeen Alliance](#)²⁶. (Note that
667 IoT frameworks are explicitly out of scope for this design; this section is for
668 background information only. See [Bluetooth wrist watch and the Internet of](#)
669 [Things](#)) It allows devices to discover and communicate with each other. It is
670 freely available (open source) and has components which run on various different
671 operating systems.

672 As a framework, it abstracts the differences between physical transports, provid-
673 ing a session API for devices to use in one-to-one or one-to-many configurations
674 for communication. A lot of its code is orientated towards implementing differ-
675 ent physical transports.

676 It provides a security API for establishing different trust models between devices.

²²<http://developer.android.com/reference/android/hardware/SensorManager.html#requestTriggerSensor%28android.hardware.TriggerEventListener,%20android.hardware.Sensor%29>

²³<https://github.com/otcshare/automotive-message-broker>

²⁴<https://github.com/otcshare/automotive-message-broker/blob/master/docs/amb.in.fidl>

²⁵<https://allseenalliance.org/framework>

²⁶<https://allseenalliance.org/>

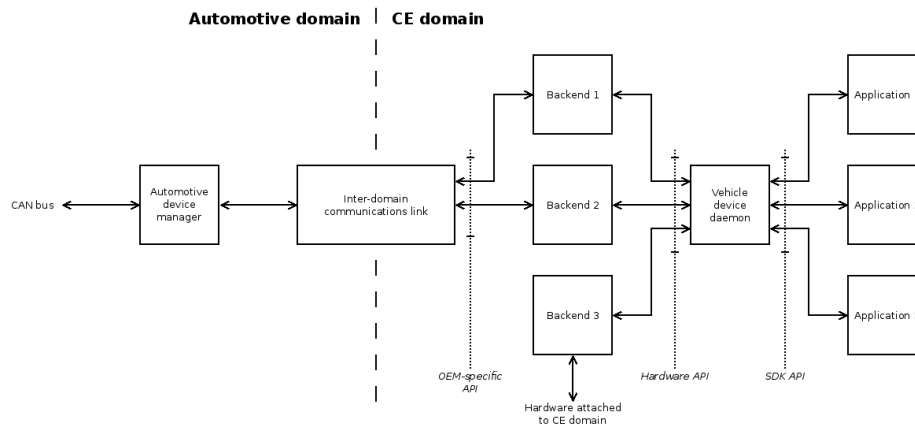

677 It provides various communication layer APIs for implementing RPC or raw
678 I/O streams (or other things in-between) between devices. However, it does not
679 specify the protocols which devices must use — they are specified by the device
680 manufacturer.

681 AllJoyn provides common services for setting up new devices, sending notifica-
682 tions between devices, and controlling devices. It provides one example service
683 for controlling lamps in a house, where each lamp manufacturer implements
684 a well-defined OEM API for their lamp, and each application uses the lamp
685 service API which abstracts over these.

686 Approach

687 Based on the above research ([Existing sensor systems](#)) and [Requirements](#), we
688 recommend the following approach as an initial sketch of a Sensors and Actua-
689 tors API.

690 Overall architecture

692 Vehicle device daemon

693 Implement a vehicle device daemon which aggregates all sensor data in the vehi-
694 cle, and multiplexes access to all actuators in the vehicle (apart from specialised
695 high bandwidth devices; see [High bandwidth or low latency sensors](#)). It will
696 connect to whichever underlying buses are used by the OEM to connect devices
697 (for example, the CAN and LIN buses); see [Hardware and app APIs](#). The im-
698 plementation may be new, or may be a modified version of ambd, although it
699 would need large amounts of rework to fit the Apertis design (see [Automotive
700 message broker](#)).

701 The daemon needs to receive and process input within the latency bounds of
702 the sensors.

703 The daemon should expose a D-Bus interface which follows the W3C [Vehicle](#)
704 [Information Access API](#)²⁷. The set of supported properties, out of those defined
705 by the [Vehicle Signal Specification](#)²⁸, may vary between vehicles — this is as ex-
706 pected by the specification. It may vary over time as devices dynamically appear
707 and disappear, which programs can monitor using the [Availability interface](#)²⁹.

708 The W3C specification was chosen rather than something like HomeKit due to
709 its close match with the requirements, its automotive background, and the fact
710 that it looks like an active and supported specification. Furthermore, HomeKit
711 requires each device to define one or more protocols to use, allowing for arbitrary
712 flexibility in how devices communicate with the controller. All the sensor and
713 actuator use cases which are relevant to vehicles need only a property interface,
714 however, which supports getting and setting properties, and being notified when
715 they change.

716 If an OEM, third party or application developer wishes to add new sensor or
717 actuator types, they should follow the [extension process](#)³⁰ and request that the
718 extensions be standardised by Apertis — they will then be released in the next
719 version of the Sensors and Actuators API, available for all applications to use. If
720 a vehicle needs to be released with those sensors or actuators in the meantime,
721 their properties must be added to the SDK API in an OEM-specific namespace.
722 Applications from the OEM can use properties from this namespace until they
723 are standardised in Apertis. See [Property naming](#).

724 Multiple vehicles can be supported by exposing new top-level instances of the
725 [Vehicle interface](#)³¹. For example, each vehicle could be exposed as a new object
726 in D-Bus, each implementing the Vehicle interface, with changes to the set of
727 vehicles notified using an interface like the standard [D-Bus ObjectManager](#)³²
728 interface.

729 This API can be exposed to application bundles in any binding language sup-
730 ported by GObject Introspection (including JavaScript), through the use of a
731 client library, just as with other Apertis services. The client library may pro-
732 vide more specific interfaces than the D-Bus interface — the D-Bus API may
733 be defined in terms of string keywords and variant values, whereas the client
734 library API may be sensor-specific strongly typed interfaces.

735 Hardware and app APIs

736 The vehicle device daemon will have two APIs: the D-Bus SDK API exposed
737 to applications, and the hardware API it consumes to provide access to the
738 CAN and LIN buses (for example). The SDK API is specified by Apertis,

²⁷http://www.w3.org/2014/automotive/vehicle_spec.html

²⁸https://github.com/GENIVI/vehicle_signal_specification

²⁹http://www.w3.org/2014/automotive/vehicle_spec.html#data-availability

³⁰https://genivi.github.io/vehicle_signal_specification/rule_set/private_branch/

³¹<https://www.w3.org/Submission/vsso/#Vehicle>

³²<http://dbus.freedesktop.org/doc/dbus-specification.html#standard-interfaces-objectmanager>

739 and is standardised across all Apertis deployments in vehicles, so that a bundle
740 written against it will work in all vehicles (subject to the availability of the
741 devices whose properties it uses).

742 **Open question:** The exact definition of the SDK API is yet to be finalised. It
743 should include support for accessing multiple properties in a single IPC round
744 trip, to reduce IPC overheads.

745 The hardware API is also specified by Apertis, and implemented by one or more
746 backend services which connect to the vehicle buses and devices and expose the
747 information as properties understandable by the vehicle device daemon, using
748 the hardware API.

749 At least one backend service must be provided by the vehicle OEM, and it must
750 expose properties from the vehicle's standard devices from the vehicle buses.
751 Other backend services may be provided by the vehicle OEM for other devices,
752 such as optional devices for premium vehicle models; or truck installations.
753 Similarly, backend services may be provided by third parties for other devices,
754 such as after-market devices like roof boxes. Application bundles may provide
755 backend services as well, to expose hardware via application-specific protocols.
756 Consequently, backend services will likely be developed in isolation from each
757 other.

758 Each backend service must expose zero or more properties — it is possible for
759 a backend to expose zero properties if the device it targets is not currently
760 connected, for example.

761 Each backend service must run as a separate process, communicating with the
762 vehicle device daemon over D-Bus using the hardware API. The hardware API
763 needs the following functionality:

- 764 • Bulk enumeration of vehicles
- 765 • Bulk notification of changes to vehicle availability
- 766 • Bulk enumeration of properties of a vehicle, including readability and
767 writability
- 768 • Bulk notification of changes to property availability, readability or
769 writability
- 770 • Subscription to and unsubscription from property change notifications
- 771 • Bulk property change notifications for subscribed properties

772 The hardware API will be roughly a similar shape to the SDK API, and hence
773 a lot of complexity of the vehicle device daemon will be in the vehicle-specific
774 backends (both operate on properties — **Properties vs devices**).

775 As vehicle networks differ, the backend used in a given vehicle has to be de-
776 veloped by the OEM developing that vehicle. Apertis may be able to provide
777 some common utility functions to help in implementing backends, but cannot

778 abstract all the differences between vehicles. (See [Background on intra-vehicle](#)
779 [networks](#)).

780 It is expected that the main backend service for a vehicle, provided by that vehi-
781 cle’s OEM, will be access the vehicle-specific network implementation running
782 in the automotive domain, and hence will use the [inter-domain communications](#)
783 [connection](#)³³. In order to avoid additional unnecessary inter-process communi-
784 cation (IPC) hops, it is suggested that the main backend service acts as *the*
785 proxy for sensor data on the inter-domain connection, rather than communicat-
786 ing with a separate proxy in the CE domain — but only if this is possible within
787 the security requirements on inter-domain connection proxies.

788 The path for a property to pass from a hardware sensor through to an application
789 is long: from the hardware sensor, to the backend service, through the D-Bus
790 daemon to the vehicle device daemon, then through the D-Bus daemon again
791 to the application. This is at least 5 IPC hops, which could introduce non-
792 negligible latency. See [High bandwidth or low latency sensors](#) for discussion
793 about this.

794 **Interactions between backend services**

795 In order to keep the security model for the system simple, backend services must
796 not be able to interact. Each device must be exposed by exactly one backend
797 service — two backend services cannot expose the same device; and neither can
798 they extend devices exposed by other backend services.

799 The vehicle device daemon must aggregate the properties exposed by its back-
800 ends and choose how to merge them. For example, if one backend service
801 provides a ‘lights’ property as an array with one element, and another backend
802 service does similarly, the vehicle device daemon should append the two and
803 expose a ‘lights’ array with both elements in the SDK API.

804 For other properties, the vehicle device daemon should combine scalar values.
805 For example, if one backend service exposes a rain sensor measurement of 4/10,
806 and another exposes a second measurement (from a separate sensor) of 6/10,
807 the SDK API should expose an aggregated rain sensor measurement of (for
808 example) 6/10 as the maximum of the two.

809 **Open question:** The exact means for aggregating each property in the Vehicle
810 Signal Specification is yet to be determined.

811 **Recommended hardware API design**

812 Below is a pseudo-code recommendation for the hardware API. It is not final,
813 but indicates the current best suggestion for the API. It has two parts — a
814 management API which is implemented by the vehicle device daemon; and a

³³<https://jwd.pages.apertis.org/apertis-website/concepts/inter-domain-communication/>

815 property API which is implemented by each backend service and queried by the
816 vehicle device daemon.

817 Types are given in the [D-Bus type system notation](#)³⁴.

818 Management API

819 Exposed on the well-known name `org.apertis.Rhodydd1` from the main daemon,
820 the `/org/apertis/Rhodydd1` object implements the standard `org.freedesktop.DBus.ObjectManager`³⁵
821 interface to let client discover and get notified about the registered vehicles.

822 Vehicles are mapped under `/org/apertis/Rhodydd1/${vehicle_id}` and implement
823 the `org.apertis.Rhodydd1.Vehicle` interface:

```
824 interface org.apertis.Rhodydd1.Vehicle {  
825     readonly property s VehicleId;  
826     method GetAttributes (  
827         in s node_path,  
828         out x current_time,  
829         out a(s(vdx)a{sv}(uu)) attributes)  
830     method GetAttributesMetadata (  
831         in s node_path,  
832         out x current_time,  
833         out a(sa{sv}(uu)) attributes_metadata)  
834     method SetAttributes (  
835         in a{sv} attributes_value)  
836     method UpdateSubscriptions (  
837         in a(sa{sv}) subscriptions,  
838         in a(sa{sv}) unsubscriptions)  
839     signal AttributesChanged (  
840         x current_time,  
841         a(s(vdx)a{sv}(uu)) changed_attributes,  
842         a(sa{sv}(uu)) invalidated_attributes)  
843     signal AttributesMetadataChanged (  
844         x current_time,  
845         a(sa{sv}(uu)) changed_attributes_metadata)  
846 }
```

847 Backends register themselves on the bus with well-known names under the
848 `org.apertis.Rhodydd1.Backends.` prefix and implement the same interfaces and
849 the main daemon, which will monitor the owned names on the bus and register
850 to the object manager signals to multiplex access to the backends.

851 Each attribute managed via the vehicle attribute API is identified by a prop-
852 erty name. Properties names come from the Vehicle Signal Specification, for

³⁴<http://dbus.freedesktop.org/doc/dbus-specification.html#type-system>

³⁵<http://dbus.freedesktop.org/doc/dbus-specification.html#standard-interfaces-objectmanager>

853 example:

- 854 • [Sunroof.Position](#)³⁶
- 855 • [Horn.IsActive](#)³⁷
- 856 • `Seat.FancySeatController.BackTemperature` (oem specific property)

857 Each attribute has three values associated:

- 858 • its value (of type v)
- 859 • its accuracy (as a standard deviation of type d, set to 0.0 for non-numeric values)
- 860 • the timestamp when it was last updated (of type x)

862 In addition the current time is also returned for comparison to the time the value was last updated.

864 Values also have two set of metadata (of type u) associated:

- 865 • availability enum
 - 866 – AVAILABLE = 1
 - 867 – NOT_SUPPORTED = 0
 - 868 – NOT_SUPPORTED_YET = 2
 - 869 – NOT_SUPPORTED_SECURITY_POLICY = 3
 - 870 – NOT_SUPPORTED_BUSINESS_POLICY = 4
 - 871 – NOT_SUPPORTED_OTHER = 5
- 872 • access flags
 - 873 – NONE = 0
 - 874 – READABLE = (1 « 0)
 - 875 – WRITABLE = (1 « 1)

876 The GetAttributes method must return the value of all properties in the given branch indicated by the node path. If the node path represents a leaf node, then only the value corresponding to that property is returned. If no such branch or property exists on that vehicle, it must return an error. To get all properties of the vehicle an empty node path shall be passed.

881 To receive notification of attribute changes via the AttributesChanged and AttributesMetadataChanged signals, clients must first register their subscription with the UpdateSubscriptions method to specify the kind of properties for which they have some interest.

885 A backend service must emit an AttributesChanged signal when one of the properties it exposes changes, but it may wait to combine that signal with those from other changed properties — the trade-off between latency and notification frequency should be determined by backend service developers.

³⁷<https://www.w3.org/Submission/vsso/#HornIsActive>

889 **Hardware API compliance testing**

890 As the vehicle-specific and third party backend services to the vehicle device
891 daemon contain a large part of the implementation of this system, there should
892 be a compliance test suite which all backend services must pass before being
893 deployed in a vehicle.

894 If a backend service is provided by an application bundle, that application bun-
895 dle must additionally undergo more stringent app store validation, potentially
896 including a requirement for security review of its code. See [Checks for backend](#)
897 [services](#).

898 The compliance test suite must be automated, and should include a variety of
899 tests to ensure that the hardware API is used correctly by the backend service.
900 It should be implemented as a mock D-Bus service which mocks up the hardware
901 management API ([Recommended hardware API design](#)), and which calls the
902 hardware property API. The backend service must be run against this mock
903 service, and call its methods as normal. The mock service should return each
904 of the possible return values for each method, including:

- 905 • Success.
- 906 • Each failure code.
- 907 • Timeouts.
- 908 • Values which are out of range.

909 It must call property API methods with various valid and invalid input.

910 The backend service must not crash or obviously misbehave (such as consuming
911 an unexpected amount of CPU time or memory).

912 As the backend service pushes data to the vehicle device daemon, the compliance
913 test could be trivially passed by a backend service which pushes zero properties
914 to it. This must not be allowed: backend services must be run under a test
915 harness which triggers all of their behaviour, for all of the devices they support.
916 Whether this harness simulates traffic on an underlying intra-vehicle network,
917 or physically provides inputs to a hardware sensor, is implementation defined.
918 The behaviour must be consistently reproducible for multiple compliance test
919 runs.

920 **SDK API compliance testing and simulation**

921 Application bundle developers will not be able to test their bundles on real
922 vehicles easily, so a simulator should be made available as part of the SDK, which
923 exposes a developer-configurable set of properties to the bundle under test. The
924 simulator must support all properties and configurations supported by the real
925 vehicle device daemon, including multiple vehicles and third-party accessories;
926 otherwise bundles will likely never be tested in such configurations. Similarly,
927 it must support varying properties over time, simulating dynamic addition and

928 removal of vehicles and devices, and simulating errors in controlling actuators
929 (for example, [Automatic window feedback](#)).

930 The emulator should be implemented as a special backend service for the vehicle
931 device daemon, which is provided by the emulator application. That way, it can
932 directly feed simulated device properties into the daemon. This backend, and
933 the emulator should only be available on the SDK, and must never be available
934 on production systems.

935 Compliance testing of application bundles is harder, but as a general principle,
936 any of the [Apertis store validation](#) checks which *can* be brought forward so they
937 can be run by the bundle developers, *should* be brought forward.

938 **SDK hardware**

939 If a developer has appropriate sensors or actuators attached to their development
940 machine, the development version of the sensors and actuators system should
941 have a separate backend service which exposes that hardware to applications
942 for development and testing, just as if it were real hardware in a vehicle.

943 This backend service must be separate from the emulator backend service (
944 [SDK API compliance testing and simulation](#)), in order to allow them to be used
945 independently.

946 **Trip logging of sensor data**

947 As well as an emulator for application developers to use when testing their
948 applications, it would be useful to provide pre-recorded ‘trip logs’ of sensor
949 data for typical driving trips which an application should be tested against.
950 These trip logs should be replayable in order to test applications.

951 The design for this is covered in the ‘Trip logging of SDK sensor data’ section
952 of the Debug and Logging design.

953 **Properties vs devices**

954 A major design decision was whether to expose individual sensors to bundles
955 via the SDK API, or to expose properties of the vehicle, which may correspond
956 to the reading from a single sensor or to the aggregate of readings from multiple
957 sensors. For example, if exposing sensors, the API would expose a gyroscope
958 plus several accelerometers, each returning individual one-dimensional measure-
959 ments. Bundles would have to process and aggregate this data themselves — in
960 the majority of cases, that would lead to duplication of code (and most likely
961 to bugs in applications where they mis-process the data), but it would also
962 allow more advanced bundles access to the raw data to do interesting things
963 with. Conversely, if exposing properties, the vehicle device daemon would pre-
964 aggregate the data so that the properties exposed to bundles are filtered and
965 averaged acceleration values in three dimensions and three angular dimensions.

966 This would simplify implementation within bundles, at the cost of preventing a
967 small class of interesting bundles from accessing the raw data they need.

968 For the sake of keeping bundles simpler, and hence with potentially fewer bugs,
969 this design exposes properties rather than sensors in the SDK API. This also
970 means that the potentially latency sensitive aggregation code happens in the
971 daemon, rather than in bundles which receive the data over D-Bus, which has
972 variable latency.

973 Similarly, the hardware API must expose properties as well, rather than indi-
974 vidual devices. It may aggregate data where appropriate (for example, if it has
975 information which is useful to the aggregation process which it cannot pass on
976 to the vehicle device daemon). This also means that a set of device semantics,
977 separate from the W3C Vehicle Data property semantics, does not have to be
978 defined; nor a mapping between it and the properties.

979 **Property naming**

980 Properties exposed in the SDK API must be named following the Vehicle Signal
981 Specification (VSS) [naming guidelines](https://genivi.github.io/vehicle_signal_specification/rule_set/basics/#addressing-nodes)³⁸. VSS defines a ‘tree-like’ logical taxon-
982 omy of the vehicle, (formally a Directed Acyclic Graph), where major vehicle
983 structures (e.g. body, engine) are near the top of the tree and the logical assem-
984 blies and components that comprise them, are defined as their child nodes. Each
985 of the child nodes in the tree is further decomposed into its logical constituents,
986 and the process is repeated until leaf nodes are reached. A leaf node is a node
987 at the end of a branch that cannot be decomposed because it represents a single
988 signal or data attribute value. For example some of the properties of DriveTrain
989 transmission and fuel system are exposed with these names:

- 990 • [Drivetrain.Transmission.Speed](#)³⁹
- 991 • [Drivetrain.Transmission.TravelledDistance](#)⁴⁰
- 992 • [DriveTrain.FuelSystem.TankCapacity](#)⁴¹

993 The element hops from the root to the leaf is called path. Properties are named
994 according to their path from the root of the tree toward the node itself and each
995 element in the path is delimited by using the dot notation.

996 Property names are formed of components in the data tree (which may contain
997 the letters a-z, A-Z, and the digits 0-9; they must start with a letter a-z or A-Z,
998 and must be in CamelCase) separated by dots. Property names must start and
999 end with a component (not a dot) and contain one or more components.

³⁸https://genivi.github.io/vehicle_signal_specification/rule_set/basics/#addressing-nodes

³⁹<https://www.w3.org/Submission/vsso/#VehicleSpeed>

⁴⁰<https://www.w3.org/Submission/vsso/#TravelledDistance>

⁴¹<https://www.w3.org/Submission/vsso/#tankCapacity>

1000 If an OEM needs to expose a custom (non-standardised) property, they must
1001 define them underneath the [private branch](#)⁴² which is provided by VSS to facil-
1002 itate OEM specific properties.

1003 **High bandwidth or low latency sensors**

1004 Sensors which provide high bandwidth outputs, or whose outputs must reach the
1005 bundle within certain latency bounds (as opposed to simply being aggregated
1006 by the vehicle device daemon within certain latency bounds), will be handled
1007 out of band. Instead of exposing the sensor data via the vehicle device daemon,
1008 the address of some out of band communications channel will be exposed. For
1009 video devices, this might be a V4L device node; for audio devices it might be a
1010 PulseAudio device identifier. Multiplexing access to the device is then delegated
1011 to the out of band mechanism.

1012 This considerably relaxes the performance requirements on the vehicle device
1013 daemon, and allows the more specialist high bandwidth use cases to be handled
1014 by more specialised code designed for the purpose.

1015 **Timestamps and uncertainty bounds**

1016 The W3C Vehicle Signal Specification does not define uncertainty fields for
1017 any of its data types (for example, [VehicleSpeed](#)⁴³ contains a single speed field
1018 measured in kilometres per hour). However, it allows the extensibility, so the
1019 data types exposed by the vehicle device daemon should all include an extension
1020 field specifying the uncertainty (accuracy) of the measurement, in appropriate
1021 units; and another specifying the timestamp when the measurement was taken,
1022 in monotonic time (in the [CLOCK_MONOTONIC](#)⁴⁴ sense).

1023 For example, the Apertis VehicleSpeed update looks like this:

```
1024 [ ('Drivetrain.Transmission.Speed',                                -> property name  
1025     (110, 0.3, 38003116),                                           -  
1026 > value field (speed, uncertainty, timestamp)  
1027     {'description': 'Latereal vehicle acceleration', -> metadata  
1028       'id': 54,  
1029       'type': 'Int32',  
1030       'unit': 'km/h'})  
1031 ]
```

1032 which represents a measurement of *speed* \pm *uncertainty* (110 \pm 0.3) kilometres
1033 per hour.

⁴²https://genivi.github.io/vehicle_signal_specification/rule_set/private_branch/

⁴³https://genivi.github.io/vehicle_signal_specification/rule_set/data_entry/sensor_actuator/

⁴⁴http://linux.die.net/man/3/clock_gettime

1034 Registering triggers and actions

1035 When subscribing to notifications for changes to a particular property using the
1036 `VehicleSignalInterface`⁴⁵ interface, a program is also subscribing to be woken up
1037 when that property changes, even if the program is suspended or otherwise not
1038 in the foreground.

1039 Once woken up, the program can process the updated property value, and poten-
1040 tially send a notification to the user. If the user interacts with this notification,
1041 the program may be brought to the foreground. The program must not be au-
1042 tomatically brought to the foreground without user interaction or it will steal
1043 the user's focus, which is distracting.

1044 See the draft compositor security design

1045 Alternatively, the program could process the updated property value in the
1046 background without notifying the user.

1047 The `VehicleSignalInterface` interface may be extended to support notifications
1048 only when a property value is in a given range; a degenerate case of this, where
1049 the upper and lower bounds of the range are equal, would support notifica-
1050 tions for property values crossing a threshold. This would most likely be imple-
1051 mented by adding optional min and max parameters to the `VehicleSignalInter-`
1052 `face.subscribe()` method.

1053 Bulk recording of sensor data

1054 This is a slightly niche use case for the moment, and can be handled by an
1055 application bundle running an agent process which is subscribed to the relevant
1056 properties and records them itself. This is less efficient than having the vehicle
1057 device daemon do it, as it means more processes waking up for changes in sensor
1058 data, but avoids questions of data formats to use and how and when to send bulk
1059 data between the vehicle device daemon and the application bundle's agent.

1060 If the implementation of this is moved into the vehicle device daemon, the
1061 lifecycle of recorded data must be considered: how space is allocated for the
1062 data's storage, when and how the application bundle is woken to process the
1063 data, and what happens when the allocated storage space is filled.

1064 Security

1065 The vehicle device daemon acts as a privilege boundary between all bundles
1066 accessing devices, between the bundles and the devices, and between each back-
1067 end service. Application bundles must request permissions to access sensor data
1068 in their manifest (see the Applications Design document), and must separately
1069 request permissions to interact with actuators. The split is because being able
1070 to control devices in the vehicle is more invasive than passively reading from

⁴⁵http://www.w3.org/2014/automotive/vehicle_spec.html#widl-VehicleSignalInterface-subscribe-unsigned-short-VehicleInterfaceCallback-callback-Zone-zone

1071 sensors — it is safety critical. A sensible security policy may be to further split
1072 out the permissions in the manifest to require specific permissions for certain
1073 types of sensors, such as cabin audio sensors or parking cameras, which have
1074 the potential to be used for tracking the user. As adding more permissions
1075 has a very low cost, the recommendation is to err on the side of finer-grained
1076 permissions.

1077 The manifest should additionally separate lists of device properties which the
1078 bundle *requires* access to from device properties which it *may* access if they
1079 exist. This will allow the Apertis store to hide bundles which require devices
1080 not supported by the user’s vehicle.

1081 From the permissions in the manifest, AppArmor and polkit rules restricting
1082 the program’s access to the vehicle device daemon’s API can be generated on
1083 installation of the bundle. See [Security domains](#) for rationale.

1084 When interacting with the vehicle device daemon, a program is securely identi-
1085 fied by its D-Bus connection credentials, which can be linked back to its man-
1086 ifest — the vehicle device daemon can therefore check which permissions the
1087 program’s bundle holds and accept or reject its access request as appropriate.
1088 Therefore, the vehicle device daemon acts as ‘the underlying operating system’ in
1089 controlling access, in the phrasing [used by](#)⁴⁶ the W3C specification. It enforces
1090 the security boundary between each bundle accessing devices, and between the
1091 intra- and inter-vehicle networks. The vehicle device daemon forms a separate
1092 security domain from any of the applications.

1093 Each backend service is a separate security domain, meaning that the vehicle
1094 device daemon is in a separate security domain from the intra-vehicle networks.

1095 The daemon may rate-limit API requests from each program in order to prevent
1096 one program monopolising the daemon’s process time and effectively causing a
1097 denial of service to other bundles by making API calls at a high rate. This
1098 could result from badly implemented programs which poll sensors rather than
1099 subscribing to change notifications from them, for example; as well as malicious
1100 bundles.

1101 Due to its complexity, low level in the operating system, and safety critical-
1102 ity, the vehicle device daemon requires careful implementation and auditing
1103 by an experienced developer with knowledge of secure software development at
1104 the operating system level and experience with relevant technologies (polkit,
1105 AppArmor, D-Bus).

1106 The threat model under consideration is that of a malicious or compromised
1107 bundle which can execute any of the D-Bus SDK APIs exposed by the daemon,
1108 with full manifest privileges for sensor access. A second threat model is that of
1109 a compromised backend service, which can execute any of the D-Bus hardware
1110 APIs exposed by the daemon.

⁴⁶http://www.w3.org/2014/automotive/vehicle_spec.html#security

1111 Security domains

1112 There are various security technologies available in Apertis for use in restricting
1113 access to sensors and actuators. See the Security Design for background on
1114 them; especially §9, Protecting the driver assistance system from attacks. These
1115 technologies can only be used on the boundaries between security domains. In
1116 this design, each application bundle is a single security domain (encompassing
1117 all programs in the bundle, including agents and helper programs); the vehicle
1118 device daemon is another domain; and each of the backend services are in a
1119 separate domain (including the vehicle networks they each use).

1120 Application bundle and another application bundle or the rest of the 1121 system

1122 Separation of the security domains of different application bundles from each
1123 other and from the rest of the system is covered in the Applications and Security
1124 designs.

1125 Application bundle and vehicle device daemon

1126 The boundary between an application bundle and the vehicle device daemon is
1127 the Sensors and Actuators SDK API, implemented by the daemon and exposed
1128 over D-Bus. The bundle's AppArmor profile will grant access to call any method
1129 on this interface if and only if the bundle requests access to one or more devices
1130 in its manifest. Note that AppArmor is not used to separate access to different
1131 sensors or actuators — it is not fine-grained enough, and is limited to allowing
1132 or denying access to the API as a whole.

1133 A separate set of [polkit](#)⁴⁷ rules for the bundle control which devices the bundle is
1134 allowed to access; these rules are generated from the bundle's manifest, looking
1135 at the specific devices listed. Given a set of polkit actions defined by the vehicle
1136 device daemon, these rules should permit those actions for the bundle.

1137 For example, the daemon could define the polkit actions:

- 1138 • org.apertis.vehicle_device_daemon.EnumerateVehicles: To list the avail-
1139 able vehicles or subscribe to notifications of changes in the list.
- 1140 • org.apertis.vehicle_device_daemon.EnumerateDevices: To list the avail-
1141 able devices on a given vehicle (passed as the vehicle variable on the ac-
1142 tion) or subscribe to notifications of changes in the list.
- 1143 • org.apertis.vehicle_device_daemon.ReadProperty: To read a property,
1144 i.e. access a sensor, or subscribe to notifications of changes to the property
1145 value. The vehicle ID and property name are passed as the vehicle and
1146 property variables on the action.

⁴⁷<http://www.freedesktop.org/software/polkit/docs/master/polkit.8.html>

- `org.apertis.vehicle_device_daemon.WriteProperty`: To write a property, i.e. operate an actuator. The vehicle ID, property name and new value are passed as the vehicle, property and value variables on the action.

The default rules for all of these actions must be `polkit.Result.NO`.

If a bundle has access to any device, it is safe and necessary to grant it access to enumerate *all* vehicles and devices (the `Enumerate*` actions above) — otherwise the bundle cannot check for the presence of the devices it requires. Knowledge of which devices are connected to the vehicle should not be especially sensitive — it is expected that there will not be a sufficient variety of devices connected to a single vehicle to allow fingerprinting of the vehicle from the device list, for example.

An application bundle, `org.example.AccelerateMyMirror`, which requests access to the `vehicle.throttlePosition.value` property (a sensor) and the `vehicle.mirror.mirrorPan` property (an actuator) would therefore have the following polkit rule generated in `/etc/polkit-1/rules.d/20-org.example.AccelerateMyMirror.rules`:

```
polkit.addRule (function (action, subject) {
    if (subject.credentials != 'org.example.AccelerateMyMirror') {
        /* This rule only applies to this bundle.
         * Defer to other rules to handle other bundles. */
        return polkit.Result.NOT_HANDLED;
    }

    if (action.id == 'org.apertis.vehicle_device_daemon.EnumerateVehicles' ||
        action.id == 'org.apertis.vehicle_device_daemon.EnumerateDevices') {
        /* Always allow these. */
        return polkit.Result.YES;
    }

    if (action.id == 'org.apertis.vehicle_device_daemon.ReadProperty' &&
        action.lookup ('property') == 'vehicle.throttlePosition.value') {
        /* Allow access to this specific property. */
        return polkit.Result.YES;
    }

    if (action.id == 'org.apertis.vehicle_device_daemon.WriteProperty' &&
        action.lookup ('property') == 'vehicle.mirror.mirrorPan') {
        /* Allow access to this specific property,
         * with user authentication. */
        return polkit.Result.AUTH_USER;
    }

    /* Deny all other accesses. */
    return polkit.Result.NO;
});
```

1191 In the rules, the subject is always the program in the bundle which is requesting
1192 access to the device.

1193 **Open question:** What is the exact security policy to implement regarding
1194 separation of sensors and actuators? For example, bundle access to sensors
1195 could always be permitted without prompting by returning `polkit.Result.YES`
1196 for all sensor accesses; but actuator accesses could always be prompted to the
1197 user by returning `polkit.Result.AUTH_SELF`. The choice here depends on the
1198 desired user experience.

1199 **Vehicle device daemon and a backend service**

1200 The boundary between the vehicle device daemon and one of its backend services
1201 is the Sensors and Actuators hardware API, implemented by the daemon and
1202 exposed over D-Bus. The backend service's AppArmor profile will grant access
1203 to call any method on this interface. Note that AppArmor is not used to grant
1204 or deny permissions to expose particular properties — it is not fine-grained
1205 enough, and is limited to allowing or denying access to the API as a whole.

1206 In order to limit the potential for a compromised backend service to escalate its
1207 compromise into providing malicious sensor data for any sensor on the system,
1208 each backend service must install a file which lists the Vehicle Data properties
1209 it might possibly ever provide to the vehicle device daemon. The vehicle device
1210 daemon must reject properties from a backend service which are not in this list.
1211 The list must not be modifiable by the backend service after installation (i.e. it
1212 must be read-only, readable by the vehicle device daemon).

1213 Furthermore, if a backend service is found to be exploitable after being deployed,
1214 it must be possible for the vehicle device daemon to disable it. This is expected
1215 to typically happen with backend services provided by application bundles, as
1216 opposed to those provided by OEMs or third parties (as these should go through
1217 stricter review, and disabling them would have a much larger impact). The
1218 vehicle device daemon must have a blacklist of backend services which it never
1219 loads. It must check the credentials of D-Bus messages from backend services
1220 against this blacklist.

1221 Using `GetConnectionCredentials`, which returns an unforgeable
1222 identifier for the peer: [http://dbus.freedesktop.org/doc/dbus-](http://dbus.freedesktop.org/doc/dbus-specification.html#bus-messages-get-connection-credentials)
1223 [specification.html#bus-messages-get-connection-credentials](http://dbus.freedesktop.org/doc/dbus-specification.html#bus-messages-get-connection-credentials)

1224 In order to support one (vulnerable) version of a backend service being black-
1225 listed, but not the next (fixed) version, the blacklist must contain version num-
1226 bers, which should be compared against the installed version number of the
1227 backend service as listed in the system-wide application bundle manifest store.

1228 **Vehicle device daemon and the rest of the system**

1229 The vehicle device daemon itself must not be able to access any of the vehicle
1230 buses or any networks. It must be run as a unique user, which owns the daemon's

1231 binary, with its DAC permissions set such that other users (except root) cannot
1232 run it. It must not have access to any device files. See §9, Protecting the driver
1233 assistance system from attacks, of the Security design for more details.

1234 **Backend service and another backend service or the rest of the system** 1235

1236 In order to guarantee it is the only program which can access a particular vehicle
1237 bus or network, each backend service should run as a unique user. The service's
1238 binary must be owned by that user, with its DAC permissions set such that
1239 other users (except root) cannot run it. Any device files which it uses for access
1240 to the underlying vehicle networks must be owned by that user, with their DAC
1241 permissions set such that other users cannot access them, and udev rules in place
1242 to prevent access by other users. If the backend needs access to a (local) network
1243 interface to communicate with the vehicle network buses, that interface must
1244 be put in a separate network namespace, and the CLONE_NEWNET flag used
1245 when spawning the backend service to put it in that namespace. This prevents
1246 the service from accessing other network interfaces; and prevents other processes
1247 from accessing the buses. See §9, Protecting the driver assistance system from
1248 attacks, of the Security design for more details.

1249 **SDK emulator**

1250 Typically, it should not be possible for one program to have access to both
1251 the vehicle device daemon's SDK API and its hardware API (this access is
1252 controlled by AppArmor). However, the SDK emulator is a special case which
1253 needs access to both — so either this must be possible as a special case, or the
1254 SDK emulator must be split into a backend service process and a UI process,
1255 which communicate via another D-Bus connection.

1256 **Apertis store validation**

1257 Application bundles which request permissions to access devices must undergo
1258 additional checks before being put on the Apertis store. This is especially im-
1259 portant for bundles which request access to actuators, as those bundles are then
1260 potentially safety critical.

1261 **Checks for access to sensors**

1262 Suggested checks for bundles requesting read access to sensors:

- 1263 • The bundle does not send privacy-sensitive data to services outside the
1264 user's control (for example, servers not operated by the user; see the [User
1265 Data Manifesto](https://userdatamanifesto.org/)⁴⁸), either via network transmission, logging to local stor-
1266 age, or other means, without the user's consent. Any data sent *with* the

⁴⁸<https://userdatamanifesto.org/>

1267 user's consent must only be sent to services which follow the User Data
 1268 Manifesto. For example (this list is not exhaustive):

- 1269 – Tracking the vehicle's movements.
- 1270 – Monitoring the user's conversations (audio recording).
- 1271 • The bundle does not have access to uniquely identifiable information, such
 1272 as a vehicle identification number (VIN). Any exceptions to this would
 1273 need stricter review.
- 1274 • The bundle clearly indicates when it is gathering privacy-sensitive data
 1275 from sensors. For example, a 'recording' light displayed in the UI when
 1276 listening using a microphone.
- 1277 1.

1278 **Checks for access to actuators**

1279 Suggested checks for bundles requesting write access to actuators:

- 1280 • The bundle does not additionally have network access.
- 1281 • Actuators are only operated while the vehicle is not driving. Any excep-
 1282 tions to this would need even stricter review.
- 1283 • Manual code review of the entire bundle's source code by a developer
 1284 with security experience. The entire source code must be made available
 1285 for review by the bundle developer, as it is all run in the same security
 1286 domain. For example (this list is not exhaustive):
- 1287 – Looking for ways the bundle could potentially be exploited by an
 1288 attacker.
- 1289 – Checking that the bundle cannot use the actuator inappropriately
 1290 during normal operation if it encounters unexpected circumstances.
 1291 (For example, checking that arithmetic bugs don't exist which could
 1292 cause an actuator to be operated at a greater magnitude than in-
 1293 tended by the bundle developer.)

1294 **Open question:** The specific set of Apertis store validation checks for bundles
 1295 which access devices is yet to be finalised.

1296 **Checks for backend services**

1297 Suggested checks for backend services for the vehicle device daemon, whether
 1298 they are provided by an OEM, a third party or as part of an application bundle:

- 1299 • The backend service does not additionally have network access.
- 1300 • The backend service does not have write access to any of the file system
 1301 except devices it needs, and the D-Bus socket.

- 1302 • The backend service cannot access any more device nodes than it needs
1303 to support its devices.
- 1304 • Manual code review of the entire bundle’s source code by a developer
1305 with security experience. The entire source code must be made available
1306 for review by the bundle developer, as it is all run in the same security
1307 domain. For example (this list is not exhaustive):
 - 1308 – Looking for ways the backend service could potentially be exploited
1309 by an attacker.
 - 1310 – Checking that the backend service cannot use any of its actuator in-
1311 appropriately during normal operation if it encounters unexpected
1312 circumstances. (For example, checking that arithmetic bugs don’t
1313 exist which could cause an actuator to be operated at a greater mag-
1314 nitude than intended by the developer.)
- 1315 • The backend service’s D-Bus service is only accessible by the vehicle device
1316 daemon (as enforced by AppArmor).
- 1317 • If other software is shipped in the same application bundle, it must be
1318 considered to be part of the same security domain as the backend service,
1319 and hence subject to the same validation checks.
- 1320 • The backend service must pass the automated compliance test ([Hardware](#)
1321 [API compliance testing](#)).
- 1322 • The backend service must not expose any properties which are not sup-
1323 ported by the version of the vehicle device daemon which it targets as its
1324 minimum dependency (see [Vehicle device daemon](#) for information about
1325 the extension process).

1326 Suggested roadmap

1327 Due to the large amount of work required to write a system like this from
1328 scratch, it is worth exploring whether it can be developed in stages.

1329 The most important parts to finalise early in development are the SDK and hard-
1330 ware APIs, as these need to be made available to bundle developers and OEMs
1331 to develop bundles and the backend services. There seems to be little scope for
1332 finalising these APIs in stages, either (for example by releasing property access
1333 APIs first, then adding vehicle and device enumeration), as that would result in
1334 early bundles which are incompatible with multi-vehicle configurations.

1335 Similarly, it does not seem to be possible to implement one of the APIs before
1336 the other. Due to the fragmented nature of access to vehicle networks, the
1337 backend needs to be written by the OEM, rather than relying on one written
1338 by Apertis for early versions of the system.

1339 Furthermore, the security implementation for the vehicle device daemon must
1340 be part of the initial release, as it is safety critical.

1341 One area where phased development is possible is in the set of properties itself
1342 — initial versions of the daemon and backends could implement a small, core
1343 set of the properties defined in the [VSS Ontology \(VSSo\)](#)⁴⁹, and future versions
1344 could expand that set of properties as time is available to implement them. As
1345 each property is a public API, it must be supported as part of the SDK one it
1346 has appeared in a released version of the daemon, so it is important to design
1347 the APIs correctly the first time.

1348 Similarly, the scope for backend services could be expanded over time. Initial
1349 releases of the system could allow only backend services written by vehicle OEMs
1350 to be used; with later releases allowing third-party backend services, then ones
1351 provided by installed application bundles.

1352 The emulator backend service ([SDK API compliance testing and simulation](#))
1353 and any SDK hardware backend services ([SDK hardware](#)) should be imple-
1354 mented early on in development, as they should be relatively simple, and hav-
1355 ing them allows application developers to start writing applications against the
1356 service.

1357 Requirements

- 1358 • [Enumeration of devices](#): The availability of known properties of the vehicle
1359 can be checked through the [Availability interface](#)⁵⁰. The W3C approach
1360 considers properties, rather than devices, to be the enumerable items, but
1361 they are mostly equivalent (see [Properties vs devices](#)).
- 1362 • [Enumeration of vehicles](#): The availability of objects implementing the
1363 W3C Vehicle interface on D-Bus is exposed using an interface like the
1364 D-Bus ObjectManager API.
- 1365 • [Retrieving data from sensors](#): Properties can be retrieved through the
1366 [VehicleInterface interface](#)⁵¹. For high bandwidth sensors, or those with
1367 latency requirements for the end-to-end connection between sensor and
1368 bundle, data is transferred out of band (see [High bandwidth or low latency](#)
1369 [sensors](#)).
- 1370 • [Sending data to actuators](#): Properties can be set through the [VehicleSig-](#)
1371 [nalInterface](#)⁵² interface. As with getting properties, data for high band-
1372 width or low latency sensors is transferred out of band.
- 1373 • [Network independence](#): The vehicle device daemon abstracts access to the
1374 underlying buses, so bundles are unaware of it.
- 1375 • [Bounded latency of processing sensor data](#): The vehicle device daemon
1376 should have its scheduling configuration set so that it can provide latency

⁴⁹<https://www.w3.org/Submission/vsso/>

⁵⁰http://www.w3.org/2014/automotive/vehicle_spec.html#data-availability

⁵¹<https://www.w3.org/Submission/vsso/#Vehicle>

⁵²http://www.w3.org/2014/automotive/vehicle_spec.html#widl-VehicleSignalInterface-subscribe-unsigned-short-VehicleInterfaceCallback-callback-Zone-zone

1377 guarantees for the underlying buses.

1378 • **Extensibility for OEMs:** Extensions are standardised through Apertis and
1379 released in the next version of the Sensors and Actuators API for use by
1380 the OEM.

1381 • **Third-party backends:** Backend services for the vehicle device daemon
1382 can be installed as part of application bundles (either built-in or store
1383 bundles).

1384 • **Third-party backend validation:** Backend services must be validated be-
1385 fore being installed as bundles (see **Checks for backend services**).

1386 • **Notifications of changes to sensor data:** Property changes are notified
1387 via a publish–subscribe interface on **VehicleSignalInterface**⁵³. Notification
1388 thresholds are supported by optional parameters on that interface.

1389 • **Uncertainty bounds:** The W3C API is extended to include uncertainty
1390 bounds for measurements.

1391 • **Failure feedback:** Through its use of **Promises**⁵⁴, the API allows for failure
1392 to set a property.

1393 • **Timestamping:** The W3C API is extended to include timestamps for mea-
1394 surements.

1395 • **Triggering bundle activation:** Programs are woken by subscriptions to
1396 property changes (see **Registering triggers and actions**).

1397 • **Bulk recording of sensor data:** **Not currently implemented**, but may
1398 be implemented in future as a straightforward extension to the API. See
1399 **Bulk recording of sensor data**.

1400 • **Sensor security:** Access to the Sensors and Actuators API is controlled by
1401 an AppArmor profile generated from permissions in the manifest. Access
1402 to individual sensors is controlled by a polkit rule generated from the same
1403 permissions. See **Security**.

1404 • **Actuator security:** As with **Sensor security**; sensors and actuators are
1405 listed and controlled by the polkit profile separately.

1406 • **App-store knowledge of device requirements:** As devices required by an
1407 application bundle are listed in the bundle’s manifest (see **Security**), the
1408 Apertis store knows whether the bundle is supported by the user’s vehicle.

1409 • **Accessing devices on multiple vehicles:** Each vehicle is exposed as a sepa-
1410 rate D-Bus object, each implementing the W3C Vehicle interface.

⁵³http://www.w3.org/2014/automotive/vehicle_spec.html#widl-VehicleSignalInterface-subscribe-unsigned-short-VehicleInterfaceCallback-callback-Zone-zone

⁵⁴<http://www.w3.org/TR/2013/WD-dom-20131107/#promises>

- **Third-party accessories:** Properties for third-party accessories must be standardised through Apertis and exposed as separate interfaces on the vehicle object on D-Bus.
- **SDK hardware support:** SDK hardware should be supported through a separate development-only backend service written specifically for that hardware.

Open questions

1. **Hardware and app APIs:** The exact definition of the SDK API is yet to be finalised. It should include support for accessing multiple properties in a single IPC round trip, to reduce IPC overheads.
2. **Interactions between backend services:** The exact means for aggregating each property in the Vehicle Data specification is yet to be determined.
3. **Security domains:** What is the exact security policy to implement regarding separation of sensors and actuators? For example, bundle access to sensors could always be permitted without prompting by returning `polkit.Result.YES` for all sensor accesses; but actuator accesses could always be prompted to the user by returning `polkit.Result.AUTH_SELF`. The choice here depends on the desired user experience.
4. **Apertis store validation:** The specific set of Apertis store validation checks for bundles which access devices is yet to be finalised.

Summary of recommendations

As discussed in the above sections, we recommend:

- Implementing a vehicle device daemon which exposes the W3C Vehicle Information Access API; this will probably need to be developed from scratch.
- Documenting the hardware API and distributing it to OEMs, third parties and application developers along with a compliance test suite and a common utility library to allow them to build backend services for accessing vehicle networks.
- Documenting the SDK API and distributing it to application bundle developers along with a validation suite and simulator to allow them to build programs which use the API.
- Provide example trip logs for journeys to test against and a method for replaying them via the vehicle device daemon, so application developers can test their applications.
- Defining how to aggregate multiple values of each property in the W3C Vehicle Data API.

- 1448 • Extending the W3C Vehicle Information Service Specification to expose
1449 uncertainty and timestamp data for each property.
- 1450 • Extending the W3C Vehicle Information Service Specification to expose
1451 multiple vehicles and notify of changes using an interface like D-Bus Ob-
1452 jectManager.
- 1453 • Extending the W3C Vehicle Information Service Specification to support
1454 a range of interest for property change notifications.
- 1455 • Adding a property to the application bundle manifest listing which device
1456 properties programs in the bundle may access if they exist.
- 1457 • Adding a property to the application bundle manifest listing which device
1458 properties programs in the bundle require access to.
- 1459 • Extending the Apertis store validation process to include relevant checks
1460 when application bundles request permissions to access sensors (privacy
1461 sensitive) or actuators (safety critical). Or when application bundles re-
1462 quest permissions to provide a vehicle device daemon backend service
1463 (safety critical).
- 1464 • Modifying the Apertis software installer to generate AppArmor rules to
1465 allow D-Bus calls to the vehicle device daemon if device properties are
1466 listed in the application bundle manifest.
- 1467 • Modifying the Apertis software installer to generate polkit rules to grant
1468 an application bundle access to specific devices listed in the application
1469 bundle manifest.
- 1470 • Implementing and auditing strict DAC and MAC protection on the vehicle
1471 device daemon and each of its backend services, and identity checks on all
1472 calls between them.
- 1473 • Defining a feedback and standardisation process for OEMs to request new
1474 properties or device types to be supported by the vehicle device daemon's
1475 API.

1476 Sensors and Actuators API

1477 This sections aims to compare the current status of the Vehicle device daemon
1478 for the sensors and actuators SDK API ([Rhodydd](https://docs.apertis.org/rhodydd/index.html)⁵⁵) with the latest W3C spec-
1479 ifications: the [Vehicle Information Service Specification](https://www.w3.org/TR/vehicle-information-service/)⁵⁶ API and the [Vehicle](https://github.com/GENIVI/vehicle_signal_specification)
1480 [Signal Specification](https://github.com/GENIVI/vehicle_signal_specification)⁵⁷ data model.

⁵⁵<https://docs.apertis.org/rhodydd/index.html>

⁵⁶<https://www.w3.org/TR/vehicle-information-service/>

⁵⁷https://github.com/GENIVI/vehicle_signal_specification

1481 It will also explain the required changes to align [Rhosydd](#)⁵⁸ to the new W3C
1482 specifications.

1483 Rhosydd API Current State

1484 The current [Rhosydd API](#)⁵⁹ is stable and usable implementing the [Vehicle Infor-](#)
1485 [mation Service Specification](#)⁶⁰ and using the data model specified by the [Vehicle](#)
1486 [Signal Specification](#)⁶¹.

1487 Considerations to align Rhosydd to the new VISS API

- 1488 1. The original Vehicle API and the Rhosydd API don't exactly match 1:1 as
1489 the latter has been adapted to follow the inter-process D-Bus constraints
1490 and best-practice, which are somewhat different than the ones for a in-
1491 process JavaScript API.

1492 New vs Old Specification

- 1493 1. The [Vehicle Data Specification](#)⁶² data model uses attributes (data) and
1494 interface objects, where VISS uses the [Vehicle Signal Specification](#)⁶³ data
1495 model which is based on a signal tree structure containing different entities
1496 types (branches, rbranches, signals, attributes, and elements).
- 1497 2. The [Vehicle Information Service Specification](#)⁶⁴ API objects are defined as
1498 JSON objects that will be passed between the client and the VIS Server,
1499 where Rhosydd is currently based on accessing attributes values using
1500 interface objects.
- 1501 3. VISS defines a set of **Request Objects** and **Response Objects** (de-
1502 fined as JSON schemas), where the client must pass request messages to
1503 the server and they should be any of the defined request objects, in the
1504 same way, the message returned by the server must be one of the defined
1505 response objects.
- 1506 4. The request and response parameters contain a number of attributes,
1507 among them the Action attribute which specify the type of action re-
1508 quested by the client or delivered by the server.
- 1509 5. VISS lists well defined actions for client requests: authorize, getMetadata,
1510 get, set, subscribe, subscription, unsubscribe, unsubscribeAll.
- 1511 6. The [Vehicle Signal Specification](#)⁶⁵ introduces the concept of **signals**. They

⁵⁸<https://docs.apertis.org/rhosydd/index.html>

⁵⁹<https://docs.apertis.org/rhosydd/index.html>

⁶⁰<https://www.w3.org/TR/vehicle-information-service/>

⁶¹https://github.com/GENIVI/vehicle_signal_specification

⁶²http://www.w3.org/2014/automotive/data_spec.html

⁶³https://github.com/GENIVI/vehicle_signal_specification

⁶⁴<https://www.w3.org/TR/vehicle-information-service/>

⁶⁵https://github.com/GENIVI/vehicle_signal_specification

are just named entities with a producer (or publisher) that can change its value over time and have a type and optionally a unit type defined.

7. The [Vehicle Signal Specification](#)⁶⁶ data model introduces a signal specification format. This specification is a YAML list in a single file called **vspec** file. This file can also be generated in other formats (JSON, FrancaIDL), and basically defines the signal and data structure tree.
8. The Vehicle Signal Specification introduces the concept of signal ID databases. These are generated from the vspec files, and they basically map signal names to ID's that can be used for easy indexing of signals without the need of providing the entire qualified signal name.

Rhodydd New Changes

- The [Vehicle Information Service Specification](#)⁶⁷ API defines the Request and Response Objects using a JSON schema format. The [Rhodydd API](#)⁶⁸ (both the application-facing and backend-facing ones) has been updated to provide a similar API based on idiomatic Dbus methods and types.
- Maps the different VISS Server actions to handle client requests to their respective Dbus methods in Rhodydd.
- The internal Rhodydd data model has been updated to support all the element types defined in the [Vehicle Signal Specification](#)⁶⁹.
- It might also be required to add support to process signal ID databases in order for Rhodydd to recognize signals specified by the Vehicle Signal Specification.

Advantages

- The new VISS spec is based on a WebSocket API, and it resembles more closely the inter-process mechanism based on D-Bus in Rhodydd rather than the previous JavaScript in-process mechanism defined by the previous specification.

Conclusion

The main effort will be about updating the internal Rhodydd data model to reflect the changes introduced in the [Vehicle Signal Specification](#)⁷⁰ data model, with the extended types and metadata.

⁶⁶https://github.com/GENIVI/vehicle_signal_specification

⁶⁷<https://www.w3.org/TR/vehicle-information-service/>

⁶⁸<https://docs.apertis.org/rhodydd/index.html>

⁶⁹https://github.com/GENIVI/vehicle_signal_specification

⁷⁰https://github.com/GENIVI/vehicle_signal_specification

1543 The DBus APIs, both on the application and backend sides, will need to be
1544 updated to map to the new data model. From a high-level point of view the
1545 old and new APIs are relatively similar, but a non-trivial amount of changes is
1546 expected to map the new concepts and to align to the new terminology.

1547 The [Rhodydd](https://docs.apertis.org/rhodydd/index.html)⁷¹ client APIs for applications (librhodydd) and backends (libcroe-
1548 sor) will need to be updated to reflect the changes in the underlying DBus
1549 APIs.

1550 Appendix: W3C API

1551 For the purposes of completeness, the [Vehicle Information Service Specifica-
1552 tion](https://www.w3.org/TR/vehicle-information-service/)⁷² is reproduced below. This is the version from the Final Business Group
1553 Report 26 June 2018, and does not include the [Vehicle Signal Specification](https://github.com/GENIVI/vehicle_signal_specification)⁷³ for
1554 brevity. The API is described as [WebIDL](http://www.w3.org/TR/WebIDL/)⁷⁴, and partial interfaces have been
1555 merged.

```
1556 [Constructor,  
1557   Constructor(VISClientOptions options)]  
1558 interface VISClient {  
1559     readonly attribute DOMString? host;
